EXAMPLE SWALLOW SCREEN

Can the patient be sat up and remain awake and alert for at least 15 minutes?

- **NO**
  - Keep nil by mouth and maintain oral hygiene. Consider artificial nutritional support. Consult dietitian as appropriate.

- **YES**
  - Is the mouth clean?
    - **NO**
      - Implement oral hygiene immediately.
    - **YES**
      - Sit patient up and give a teaspoon of water x3. Place fingers on midline above and below the larynx and feel the swallow. Observe each teaspoon.
        - Are any of these signs present?
          - Absent swallow
          - Cough
          - Delayed cough
          - Altered voice quality
          - (ask the patient to say "Aah")
        - **NO**
          - Observe the patient continuously drink a glass of water.
            - Are any of these signs present?
              - Absent swallow
              - Cough
              - Delayed cough
              - Altered voice quality
              - (ask the patient to say "Aah")
            - **NO**
              - Start feeding (soft options) with caution.
                - Continue to observe for coughing or development of a chest infection and refer to Speech and Language Therapy as necessary.
            - **YES**
              - Keep nil by mouth and refer to Speech and Language Therapist.
          - **YES**
            - Keep nil by mouth and refer to Speech and Language Therapist.
**EVALUATING SWALLOWING AND NUTRITION AFTER STROKE**

Dysphagia affects a large proportion of stroke patients. Swallowing difficulties can result in aspiration and reduced oral intake, leading to the potentially serious complications of pneumonia, undernutrition and dehydration.

**ASPIRATION PNEUMONIA**

- The water swallow test should be used as part of the screening for aspiration risk in stroke patients.
- Clinical history taking should take into account comorbidities and other risk factors (e.g., smoking, respiratory disease) to identify increased risk of developing aspiration pneumonia.

**SWALLOW SCREENING**

- Patients with dysphagia should be monitored daily in the first week to identify rapid recovery. Observations should be recorded as part of the care plan.
- Patients not fit for assessment should be screened daily to avoid delay in referral for full clinical assessment.
- A typical swallow screening procedure should include:
  - initial observations of the patient's consciousness level
  - observations of the degree of postural control
  - if the patient is able to actively cooperate and is able to be supported in an upright position the procedure should also include:
    - observations of oral hygiene
    - observations of control of oral secretions
    - if appropriate, a water swallow test.

**DIET MODIFICATION**

- Advice on diet modification and compensatory techniques (postures and manoeuvres) should be given following full swallowing assessment.
- Texture modified food should be attractively presented and appetising. Patients should have a choice of dishes.
- Texture modified meals may be fortified to enable patients to meet nutritional requirements.
- Food and fluid intake should be monitored and, if indicated, a referral made to the dietitian.

**DYSPHAGIA THERAPY**

- All patients who have dysphagia for more than one week should be assessed to determine their suitability for a rehabilitative swallowing therapy programme. Consideration should be given to:
  - the nature of the underlying swallowing impairment
  - patient suitability in terms of motivation and cognitive status.
- Patients with dysphagia should have an oropharyngeal swallowing rehabilitation programme that includes restorative exercises in addition to compensatory techniques and diet modification.

**NUTRITIONAL SCREENING**

- Assessment of nutritional risk should be carried out within the first 48 hours with regular re-assessment thereafter during the patient’s recovery and be recorded prior to any discharge.
- Assessment of a patient's nutritional risk should include an assessment of their ability to eat independently and a periodic record of their food consumption.
- Ongoing monitoring of nutritional status should include a combination of the following parameters:
  - biochemical measures (e.g., low pre-albumin, impaired glucose metabolism)
  - swallowing status
  - unintentional weight loss
  - eating assessment and dependence
  - nutritional intake.
- Nutritional screening should cover body mass index (BMI), ability to eat, appetite, physical condition, mental condition.

**NUTRITIONAL INTERVENTIONS**

- Following nutritional screening, those identified as undernourished, and those at risk of becoming undernourished, should be referred to a dietitian and considered for prescription of oral nutritional supplements as part of their overall nutritional care plan.
- Patients with dysphagia who are unable to meet their nutritional requirements orally should be considered for initial NG feeding as soon as possible, within one week of onset. This decision should be made by the multidisciplinary team in consultation with the patient and their carers/family.
- Patients in the early recovery phase should be reviewed weekly by the multidisciplinary team to ascertain if long term (>4 weeks) feeding is required.
- Feeding via percutaneous endoscopic gastrostomy (PEG) in the recommended feeding route for long term (>4 weeks) enteral feeding. Patients requiring long term tube feeding should be reviewed regularly.
- Patients' and carer's perceptions and expectations of PEG feeding should be taken into account and the benefits, risks and burden of care fully explained before initiating feeding.

**ROLE OF REGULAR REVIEW**

- Patients with persistent dysphagia should be reviewed regularly, at a frequency related to their individual swallowing function and dietary intake, by a professional skilled in the management of dysphagia.

**ORAL HYGIENE**

- Good oral hygiene should be maintained in patients with dysphagia, particularly in those with PEG or NG tubes, in order to promote oral health and patient comfort.
- An appropriate oral care protocol should be used for every patient with dysphagia, including those who use dentures.

**CARING FOR PATIENTS WITH DYSPHAGIA**

- Staff, carers and patients should be trained in feeding techniques. This training should include:
  - modifications of positioning and diet
  - food placement
  - management of behavioural and environmental factors
  - delivery of oral care
  - management of choking.

This Quick Reference Guide provides a summary of the main recommendations in SIGN 119 Management of patients with stroke: Identification and management of dysphagia.

Recommendations are graded A B C D to indicate the strength of the supporting evidence. Good practice points E are provided where the guideline development group wishes to highlight specific aspects of accepted clinical practice. Details of the evidence supporting these recommendations can be found in the full guideline, available on the SIGN website: www.sign.ac.uk
